$$dB_{f(t)} = \sqrt{f'(t)}dB_t$$

Loo into hornstin olbeck process Understand Stationatiy (strong and weak) Resad about ARMA and ARIMA what they mean, what they do, and differences

1.1 Reading 2/19-2/26

Definition (Ergodic Property with a constant limit). also known as EPCL

$$\exists \mu \in \mathbb{R} \text{ s.t. } \mathbb{P}(\lim_{n \rightarrow \infty} \bar{x} = \mu) = 1$$

where $\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$

Definition (L^2 - Ergodic propetty with a constant limit). also known as L^2 -EPCL

$$\exists \mu \in \mathbb{R} \text{ s.t. } \lim_{n \rightarrow \infty} \mathbb{E}((\bar{x} - \mu)^2) = 0$$

EPLC doesnt hold in a lack of stablilty, high variabilty of marginal distributions, and absobsing states.

Definition (Strict Stationarity). $X_t \in \mathbb{R}(t \in \mathbb{Z})$ is said to be strictly stationary if

$$\forall k \in \mathbb{Z}, \forall m \in \mathbb{N}, \forall t_1, t_2, \dots, t_m \in \mathbb{Z}$$

$$(X)_{t_1}, (X)_{t_2}, \dots, (X)_{t_m} =_d (X)_{t_1+k}, (X)_{t_2+k}, \dots, (X)_{t_m+k}$$

In other words, the collection of distributions of the random variables $(X)_{t_1}, (X)_{t_2}, \dots, (X)_{t_m}$ is the same as the collection of distributions of the random variables shifted over $(X)_{t_1+k}, (X)_{t_2+k}, \dots, (X)_{t_m+k}$

Example (Moverage Average Process of order q). $X_t = \sum_{j=0}^q \psi_j \epsilon_{t-j}(t \in \mathbb{Z})$ where $\epsilon_t \in \mathbb{R}$ iid, $\psi_j \in \mathbb{R}$ and $j = 0, 1, \dots, q$.

Definition (Weak Stationarity). Let $X_t \in \mathbb{R}(t \in \mathbb{Z})$ s.t. $\forall t \in \mathbb{Z}, \mathbb{E}(|X_t|) < \infty$

Then $\mu_t = \mathbb{E}(X_t)$ is called the expected balue funtion or mean function of the process.

IF $E(x_t^2) < \infty$ then $\gamma : \mathbb{Z} \times \mathbb{Z} \rightarrow \mathbb{R}$ with $\gamma(s, t) = \text{Cov}(X_s, X_t)$ is called the autocovariance function of the process. (acf)

Also $\mathbb{E}(X_s - \mu_s)(X_t - \mu_t) = \text{Cov}(X_s, X_t)$

Additionally

$$\rho(s, t) = \text{corr}(X_s, X_t) = \frac{\text{Cov}(X_s, X_t)}{\sqrt{\text{Var}(X_s)\text{Var}(X_t)}}$$

is called the autocorrelation function of the process. (acf)

We can also say something is weakly stationary if

$$\mathbb{E}X_t^2 < \infty$$

$$\exists \mu \in \mathbb{R} \text{ s.t. } \mathbb{E}(X_t) = \mu$$

$$\exists \gamma : \mathbb{Z} \rightarrow \mathbb{R} \text{ s.t. } \forall s, t \in \mathbb{Z} : \text{Cov}(X_s, X_t) = \gamma(t - s)$$

Definition (k-step prediction mean squared error). Let $\mathcal{F}_{\leq t} = \sigma(X_s, s \leq t)$
 $\mathcal{X}_t = \{Y | Y \in L^2(\Omega), \mathcal{F}_{\leq t} - \text{measurable}\}$

Then the k -step prediction mean squared error is defined for $k \geq 1$ and $Y \in \mathcal{X}_t$ as

$$\sigma_k^2(Y) = \mathbb{E}((X_{t+k} - Y)^2)$$

ASK to explain thm 2.1 (pg 23) and thm 2.2 (pg 24)

Definition (Orthogonal Complement). Let $(H, \langle \cdot, \cdot \rangle)$ be a Hilbert space and $A \subseteq H$ be a closed subspace of H .

The orthogonal complement of A is defined as

$$A^\perp = \{x : x \in H \text{ s.t. } \forall y \in A : \langle x, y \rangle = 0\}$$

We also write $A \perp B \iff \forall x \in A, y \in B : \langle x, y \rangle = 0$

Note that A^\perp is a closed linear subspace of H

Dont understand the implications of corollary 2.3 pg 26

Definition (Optimal Forecast). Let $X_t \in \mathbb{R}(t \in \mathbb{Z})$ be a weakly stationary process.

$$\begin{aligned} \mathcal{F}_{\leq t} &= \sigma(X_s : s \leq t) \\ \mathcal{X}_t &= \{Y | Y \in L^2(\Omega), \mathcal{F}_{\leq t} - \text{measurable}\} \\ k \in \mathbb{N}, \hat{X}_{t+k} &\in \mathcal{X}_t \end{aligned}$$

Then \hat{X}_{t+k} is the optimal forecast of X_{t+k} given the information up to time t (i.e. $\mathcal{F}_{\leq t}$)

$$\iff$$

$$\sigma_k^2(\hat{X}_{t+k}) = \inf_{Y \in \mathcal{X}_t} \sigma^2(Y)$$

Definition (Conditional Expectation). A \mathcal{G} -measurable random variable Y is said to be the conditional expectation of X given \mathcal{G} if

$$\begin{aligned} \mathbb{E}(X|\mathcal{G}) &= Y \\ \iff \forall A \in \mathcal{G} : \int_A X dP &= \int_A Y dP \end{aligned}$$

Note: $\mathbb{E}(X|\mathcal{G})$ is a \mathcal{G} -measurable random variable.

Corollary.

$X_t \in \mathbb{R}(t \in \mathbb{Z})$ is a weakly stationary process)

$$\hat{X}_{t+k} \in \mathcal{X}_t$$

$$\sigma_k^2(\hat{X}_{t+k}) = \inf_{Y \in \mathcal{X}_t} \sigma^2(Y) \iff \hat{X}_{t+k} = \mathbb{E}(X_{t+k} | \mathcal{F}_{\leq t})$$

In other words the optimal forecast of X_{t+k} given the information up to time t is the conditional expectation of X_{t+k} given $\mathcal{F}_{\leq t}$

Definition (Infinte linear past of X_t).

$$L_t^0 = \left\{ Y \mid Y = \sum_{j=1}^k a_j X_{t_j}, k \in \mathbb{N}, a_j \in \mathbb{R}, t_j \in \mathbb{Z}, t_j \leq t \right\}$$

$$L_t = \overline{L_t^0} = \left\{ Y \mid \exists Y \in L_t^0 (n \in \mathbb{N}) \text{ s.t. } \lim_{n \rightarrow \infty} \|Y - Y_n\|_{L^2(\Omega)}^2 = 0 \right\}$$

$$L_{-\infty} = \bigcap_{t=-\infty}^{\infty} L_t = \text{infinite linear past of } X_t$$

Definition (Optimal Linear Forecast of X_{t+k} given $\mathcal{F}_{\leq t}$). Let $X_t \in \mathbb{R}(t \in \mathbb{Z})$ be a weakly stationary process with $k \geq 1$ and $\hat{X}_{t+k} \in L_t$
Then

$$\hat{X}_{t+k} = \text{optimal linear forecast of } X_{t+k} \text{ given } \mathcal{F}_{\leq t}$$

$$\iff$$

$$\sigma_k^2(\hat{X}_{t+k}) = \inf_{Y \in \mathcal{X}_t} \sigma^2(Y)$$

Definition (Deterministic Stochastic). Let $X_t \in \mathbb{R}(t \in \mathbb{Z})$ be a weakly stationary process. It is called deterministic if $\sigma_k^2(X_{t+k}) = 0$
More generally:

$$\forall t \in \mathbb{Z} : \inf_{Y \in L_t} \mathbb{E} [(Z_{t+1} - Y)^2] = 0$$

Theorem 1 (Wold Decomposition Theorem). Let $X_t \in \mathbb{R}(t \in \mathbb{Z})$ be a weakly stationary process.
Then

$$\exists a_0, a_1, a_2, \dots \text{ s.t. } a_0 = 1, \sum_{j=1}^{\infty} a_j^2 < \infty$$

and

$$\exists \epsilon_t, \mu_t (t \in \mathbb{Z}) \text{ s.t. } \forall s, t \in \mathbb{Z} :$$

$$\epsilon_t \in L_t, \mu_t \in L_{-\infty}$$

$$E(\epsilon_t) = 0, \text{Cov}(\epsilon_s, \epsilon_t) \sigma_{\epsilon}^2 \delta_{s,t} \leq \infty, \text{Cov}(\epsilon_s, \mu_t) = 0$$

$$X_{t_{a.s., L^2(\Omega)}} = \mu_t + \sum_{j=0}^{\infty} a_j \epsilon_{t-j} (t \in \mathbb{Z})$$

pg(26/34) This is literally fourier series for time series.
<https://math.stackexchange.com/questions/703246/i-have-trouble-understanding-the-proof-of-the-wold-decomposition-theorem>

Definition (Purely Stochastic or Regular). We say if X_t has wold decomposition with $\mu_t \equiv \mu \in \mathbb{R}, \sigma_\epsilon^2 > 0$
Then X_t is called purely stochastic or regular.

Definition. Let $a = \{a_j\}_{j \in \mathbb{N}} \in \mathbb{R}^{\mathbb{N}}$, $0 < \beta < \infty$
Then

$$\|a\|_{\ell^\beta} = \left(\sum_{j=1}^{\infty} |a_j|^\beta \right)^{\frac{1}{\beta}} < \infty$$

Definition (Future and Asymptotic events).

$\mathcal{F}_t (t \in \mathbb{Z}) =$ sequence of σ -algebras on Ω

$\mathcal{F}_{>t} = \sigma \left(\bigcup_{s=t+1}^{\infty} \mathcal{F}_s \right)$ future events

$\mathcal{F}^\infty = \bigcap_{t=1}^{\infty} \mathcal{F}_{>t}$ asymptotic events

Definition (Ergodic Processes). Let $X_t (t \in \mathbb{Z})$ be \mathcal{F}_t -measurable.

X_t is an Ergodic process

$$\Longleftrightarrow$$

$$\forall B \in \mathcal{F}^\infty : \mathbb{P}^2(B) = \mathbb{P}(B)$$

$$\Longleftrightarrow$$

$$\forall B \in \mathcal{F}^\infty : \mathbb{P}(B) \in \{0, 1\}$$

Theorem 2 (Kolmogorov's 0-1 Law).

$$X_t(t \in \mathbb{Z}) \text{ iid} \implies X_t \text{ is ergodic}$$

Theorem 3 (Birkhoff's Ergodic Theorem).

$$X_t(t \in \mathbb{Z}) \text{ strictly stationary, ergodic, } \mathbb{E}(|X_t|) < \infty$$

$$\implies$$

$$\mu = E(X_t) \in \mathbb{R} \text{ and } \bar{x} \rightarrow \mu \text{ a.s.}$$

2 2/26

Definition (Fockker Plank).

$$\frac{dp(t, x)}{dt} = \frac{d}{dx}(\mu(t, x)p(t, x)) + \frac{d^2}{dx^2}(\sigma(t, x)p(t, x))$$

where $p(t, x)$ is the probability density function of the process X_t

Definition ($B_{f(t)}$). $dB_{f(t)} = \sqrt{f'(t)}dB_t$

$$X_t = \frac{B_{e^t}}{\sqrt{e^t}}$$

$$dX_t = \frac{dB_{e^t}}{e^{t/2}} + \frac{B_{e^t}}{d}e^{-t/2} + \{$$

Look through example of Random walk +1,-1 and the linear past of it.

2.1 Reading 2/26-3/5

Definition (A1-A4).

$$\forall t \in \mathbb{Z} : \mu_t = \mathbb{E}(X_t) \in \mathbb{R} \quad (1)$$

$$\forall t \in \mathbb{Z} : \sigma_t^2 = \text{Var}(X_t) < \infty \quad (2)$$

$$\exists \mu \in \mathbb{R} \text{ s.t. } \lim_{t \rightarrow \infty} \mu_t = \mu \quad (3)$$

$$\lim_{t \rightarrow \infty} \text{cov}(\bar{x}_n, X_n) = 0 \quad (4)$$

Weak stationarity implies A1-A3

$$\lim_{k \rightarrow \infty} \gamma_X(k) = 0$$

$\gamma_X(k)$ Cesaro summable with limit 0

$$\lim_{k \rightarrow \infty} \text{Cov}(\bar{x}_n, X_n) = \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{k=1}^{n-1} \gamma_X(k) = 0 \quad A4$$

This is an implication from top to bottom for A4

Definition (Backshift/ Lag Operator).

$$B : \mathbb{R}^{\mathbb{Z}} \rightarrow \mathbb{R}^{\mathbb{Z}}$$

$$x = \{x_t\}_{t \in \mathbb{Z}} \rightarrow y = Bx$$

$$\text{with } y_t = x_{t-1}$$

This shifts the sequence to the left by 1.

Definition (Linear Process). $X_t \in \mathbb{R}(t \in \mathbb{Z}), \mathbb{E}(X_t) = \mu \in \mathbb{R}$ is a linear cprocess in $L^2(\Omega)$ if

$$\exists \epsilon_t \in \mathbb{R}(t \in \mathbb{Z}) \text{ iid } \mathbb{E}(\epsilon_t) = 0, \sigma_\epsilon^2 = \text{var}(\epsilon_t) < \infty$$

and

$$\exists a_j \in \mathbb{R}(j \in \mathbb{Z}), \sum_{j=-\infty}^{\infty} a_j^2 < \infty$$

s.t.

$$\forall t \in \mathbb{Z} : \lim_{N \rightarrow \infty} \|X_t - X_{t,N}\|_{L^2(\Omega)}^2 = 0$$

We then write

$$X_t = \mu + \sum_{j=-\infty}^{\infty} a_j \epsilon_{t-j}(t \in \mathbb{Z}) = \mu + \left(\sum_{j=-\infty}^{\infty} a_j B^j \right) \epsilon_t$$

If $a_j = 0$ for $j < 0$ then we call it a causal linear process.

By definition if X_t is a linear process then it is weakly and strictly stationary.

NOTE: I am skipping most of the rest of the specific assumptions in favor of Reading more Probability Measures for Time Series
